Identified in Wuhan, China in December 2019.
Caused by the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2).

In the United States alone, we currently have

- **37,768,911** total cases
- **626,833** total deaths

Transmission by exposure to infectious respiratory fluids:

1. Inhalation of virus
2. Deposition of virus on exposed mucus membranes
3. Touching mucous membranes with soiled hands contaminated with virus

COVID-19 weekly cases per 100,000 population by race/ethnicity, United States

COVID-19 weekly case rate per 100,000 population by percentage of county population in poverty, United States

Why make a mathematical study of COVID-19?

An epidemic model provides . . .

- a convenient summary of the data
- insight into the underlying processes of the disease spread
- a testing ground for assessing control procedures

Models of infectious diseases are usually variations on the **Kermack-McKendrick model** (1927).

Usual assumptions:

- Population is *homogeneous*
- Transmission is spatially independent

Project Context and Objectives

These assumptions don't match reality!

Level of community transmission by county

(a) 7/22/2021

(b) 7/29/2021

(c) 8/8/2021

(d) 8/21/2021

Idea: Use reaction-diffusion to build a spatially explicit model.

- The data clearly shows a diffusive pattern
- Spatial dependence can approximate demographic differences
- Spatially dependent data exists for many scales and regions

- ② Project Context and Objectives
- ③ Social and Community Connections**
- ④ Current Work

Original context: Working with David Eads (NPR) to identify *demographic trends* in COVID-19.
What are the effects of **age** and **race/ethnicity** in the Chicago area?
